

## 6 Autokey Ciphers

The first one to propose autokey ciphers was BELASO in 1564. Also this cipher is often attributed to VIGENÈRE.

### Encryption and Decryption

The alphabet  $\Sigma$  is equipped with a group operation  $*$ . As key chose a string  $k \in \Sigma^l$  of length  $l$ . For encrypting a plaintext  $a \in \Sigma^r$  one concatenates  $k$  and  $a$  and truncates this string to  $r$  letters. This truncated string then serves as keytext for a running-key encryption:

|             |       |       |         |           |       |         |             |
|-------------|-------|-------|---------|-----------|-------|---------|-------------|
| Plaintext:  | $a_0$ | $a_1$ | $\dots$ | $a_{l-1}$ | $a_l$ | $\dots$ | $a_{r-1}$   |
| Keytext:    | $k_0$ | $k_1$ | $\dots$ | $k_{l-1}$ | $a_0$ | $\dots$ | $a_{r-l-1}$ |
| Ciphertext: | $c_0$ | $c_1$ | $\dots$ | $c_{l-1}$ | $c_l$ | $\dots$ | $c_{r-1}$   |

The formula for encryption is

$$c_i = \begin{cases} a_i * k_i & \text{for } i = 0, \dots, l-1, \\ a_i * a_{i-l} & \text{for } i = l, \dots, r-1. \end{cases}$$

**Example,**  $\Sigma = \{A, \dots, Z\}$ ,  $l = 2$ ,  $k = XY$ :

|       |   |   |   |   |   |   |   |   |
|-------|---|---|---|---|---|---|---|---|
| P     | L | A | I | N | T | E | X | T |
| X     | Y | P | L | A | I | N | T | E |
| ----- |   |   |   |   |   |   |   |   |
| M     | J | P | T | N | B | R | Q | X |

**Remark:** Instead of the standard alphabet (or the TRITHEMIUS table) one could also use a permuted primary alphabet.

Here is the formula for decryption

$$a_i = \begin{cases} c_i * k_i^{-1} & \text{for } i = 0, \dots, l-1, \\ c_i * a_{i-l}^{-1} & \text{for } i = l, \dots, r-1. \end{cases}$$

A Perl program is `autokey.pl` in the web directory <http://www.staff.uni-mainz.de/pommeren/Cryptology/Classic/Perl/>.

### Approaches to Cryptanalysis

The four most promising approaches are:

- Exhaustion for small  $l$ .
- Interpretation as running-key cipher from position  $l$ , in case of a key word or phrase from the plaintext language even from the beginning of the ciphertext:

- Probable word and zigzag exhaustion
- Frequent word fragments
- Frequency analysis
- Frequent letter combinations

The repetition of the plaintext in the key makes the task considerably easier.

- Similarity with the TRITHEMIUS-BELASO cipher, see Section 8 below
- Algebraic cryptanalysis (for known plaintext): Solving equations. We describe this for a commutative group, the group operation written as addition, that is, we consider  $\Sigma$ ,  $\Sigma^r$ , and  $\Sigma^{r+l}$  as  $\mathbb{Z}$ -modules.

We interpret the encryption formula as a system of linear equations with an  $r \times (r + l)$  coefficient matrix:

$$\begin{pmatrix} c_0 \\ c_1 \\ \vdots \\ c_{l-1} \\ c_l \\ \vdots \\ c_{r-1} \end{pmatrix} = \begin{pmatrix} 1 & 0 & \dots & 1 & & \\ & 1 & 0 & \dots & 1 & \\ & & \ddots & \ddots & & \ddots \\ & & & 1 & 0 & \dots & 1 \end{pmatrix} \begin{pmatrix} k_0 \\ k_1 \\ \vdots \\ k_{l-1} \\ a_0 \\ \vdots \\ a_{r-1} \end{pmatrix}$$

This is a system of  $r$  linear equations with the  $r + l$  unknowns (the components of)  $k \in \Sigma^l$  and  $a \in \Sigma^r$ . “In general” such a system is solvable as soon as  $l$  of the unknowns are guessed, that means known plaintext of length  $l$  (not necessarily connected). Since the involved  $\mathbb{Z}$ -modules are (in most interesting cases) not vector spaces, solving linear equations is a bit intricate but feasible. This is comprehensively treated in the next chapter.

### Ciphertext Autokey

Using ciphertext instead of plaintext as extension of the  $l$ -letter key is a useless variant, but also proposed by VIGENÈRE. We only describe it by an example:

**Example,**  $\Sigma = \{A, \dots, Z\}$ ,  $l = 2$ ,  $k = XY$ :

|   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|
| P | L | A | I | N | T | E | X | T |
| X | Y | M | J | M | R | Z | K | D |
|   |   |   |   |   |   |   |   |   |
| M | J | M | R | Z | K | D | H | W |

**Exercise.** Give a formal description of this cipher. Why is cryptanalysis almost trivial? Work out an algorithm for cryptanalysis.

**Exercise.** Apply your algorithm to the cryptogram

IHTYE VNQEW KOGIV MZVPM WRIXD OSDIX FKJRM HZBVR TLKMS FEUKE  
VSIVK GZNUX KMWEP OQEDV RARBX NUJJX BTMQB ZT

**Remark:** Using a nonstandard alphabet makes this cipher a bit stronger.
